

Subsystem B Cross-Review: Bruce

Subsystem B implements a Virtual Memory Simulator that demonstrates how an OS can manage physical memory using paging and page replacement algorithms. It clearly shows the “Page Fault” cycle: Check Table - Fault - Find Victim - Evict - Load - Update Stats.

The design of this program makes effective use of the Standard Template Library (STL). It also separates the First In First Out (FIFO) and Least Recently Used (LRU) logic, making it easier to compare how they choose which page to kick out when the memory is full. Overall, this subsystem effectively demonstrates the core mechanics of memory management.
