

Subsystem A Cross Review: Fletcher and Amir

Subsystem A. demonstrates the implementation of CPU scheduling concepts for algorithms such as FCFS, Round Robin, and Priority scheduling. This subsystem is well organized due to the shared scheduler being separated from the individual scheduling algorithms, making the code easier to maintain and extend. The testing structure is also done very well since it checks lifecycle management, process creation and scheduling behavior. Also implements error handling.

The subsystem demonstrates how different scheduling algorithms behave under different conditions while being easy to understand and test. However, it does not seem to be an advanced operating system due to its behaviors like multithreading and context switching. Overall, the subsystem succeeds in providing a clear and educational simulation of CPU scheduling and process management concepts.
